

A The evidence set (identical everywhere)

19-year-old female

true diagnosis: Guillain-Barré syndrome

e1 Recently had a viral infection

e2 Shortness of breath, significant

e3 Weakness in facial muscles and/or eyes

e4 Weakness in both arms and/or both legs

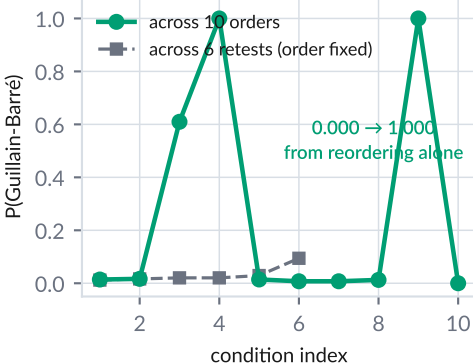

e5 Numbness / tingling in the feet

e6 Weakness or paralysis on one side of the face

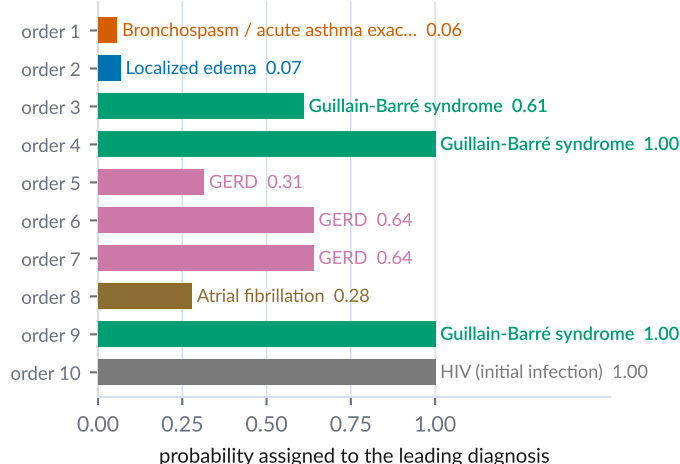

e7 No travel outside the country in 4 weeks

Textbook presentation: post-viral, ascending bilateral weakness, facial weakness, distal paraesthesia.

C Probability on the correct diagnosis

B Ten orders of that set — six different answers

D It names the diagnosis correctly every time

Named diagnosis (one index asked) **Guillain-Barré 18 / 18**

Stated posterior ranks it first **3 / 10 orders**

Mean pairwise JSD across orders **0.593**

Mean pairwise JSD, retests (floor) **0.048**

Order effect above this model's floor **0.545**

The information is present: the model states it when asked for a name. What moves with order is the probability it puts on it.
